

Simple Query and Forwarded Query

There are two types of queries according to whether a query is executed across cluster nodes or not.

We call a query which is executed across cluster nodes **forwarded query**, meaning that TajoMaster forwards the query to a query master. In contrast, we call a query without distributed execution **simple query** or **non-forwarded query**, which executed in only client side. The following query is an example of simple query.

```
select * from table limit 10;
```
