CLion setup for MXNet C++ development on Mac and Linux___

1.2. Configure SSH for GitHub
1.3. Install git-secrets
1.4. Install Xcode
Step 2. Get the MXNet codebase
2.1. Fork the Apache MXNet repository
2.2. Clone your fork on your machine
Step 3. Install additional tools
 3.1. Install CMake
3.2. Install a compiler
 Option 1. Install LLVM
 Option 2. Install gcc
3.3. Install ccache
3.4. Install jemalloc
Step 4. CLion setup
4.1. Select toolchain
4.2. Build configuration
4.3. Set CMake options
4.4. Run tests

1.1. Install and configure git

Step 1. Install prerequisites

- 4.4. Kull tests
- Step 5. Select a style file (optional)
 5.1. Loading a style file
- B. Remote host development

This page will guide you through the process of setting up CLion for MXNet C++ development on Mac. It covers two different setups: a local one, where both the coding and building are done in your laptop, and a remote setup. This second option is based on a new feature in CLion v2018.3 which enables remote project support.

A. Local setup

• A. Local setup

Step 1. Install prerequisites

These are not required, but they are recommended practices. The next steps assume that Homebrew, the package manager manager for macOS, is installed in your device. Otherwise, it can easily be installed by running the following command:

```
/usr/bin/ruby -e "$(curl -fsSL https://raw.githubusercontent.com/Homebrew/install/master/install)"
```

1.1. Install and configure git

```
brew install git
git config --global user.name "<USERNAME>"
```

1.2. Configure SSH for GitHub

Using SSH, you can connect to GitHub without having to input your credentials every time yo do so. This is not necessary, but it is convenient and time saving in the long run. The steps to configure SSH for this task can be found on GitHub's FAQ.

1.3. Install git-secrets

Git-secrets is a tool that prevents you from committing passwords or sensitive information to your repository. More information can be found on git-secrets' GitHub repo.

```
brew install git-secrets
```

After installing git-secrets, you must install the hooks for every repo that you wish to use with git secrets install.

1.4. Install Xcode

Download and install Xcode, which contains a suite of software development tools by Apple. It also includes the Xcode IDE, although here we will use CLion as IDE instead. Newer versions of Xcode might not be compatible with your macOS version, you can check the requirements here.

To download an older version of Xcode, scroll down in the downloads page and click the See more downloads link.
 Next, you will need to accept Xcode's license. It can be done from the command line:
 sudo xcodebuild -license accept

Step 2. Get the MXNet codebase

Once you have installed the required tools, it is time to get the project's code.

2.1. Fork the Apache MXNet repository

MXNet is hosted in a GitHub repository, incubator-mxnet. The best practice for development is to fork this repository and work on your local copy.

- Go to https://github.com/apache/incubator-mxnet
- · Click the fork button on the top right.

2.2. Clone your fork on your machine

git clone --recursive https://github.com/<YOUR GITHUB USERNAME>/incubator-mxnet

Next, set git secrets to track the repository with git secrets install.

```
cd incubator-mxnet git secrets install
```

Once the repo is being tracked, you can add different prohibited patterns for git-secrets to control. Check the documentation for further instructions on how to add patterns, exceptions and other utilities.

Step 3. Install additional tools

Before installing CLion, there is a set of tools for compiling C++ projects which we need to install.

3.1. Install CMake

CMake is an application to manage builds in a compiler independent way. Installing it with Homebrew is straightforward:

brew install cmake

3.2. Install a compiler

MXNet uses OpenMP, an API for high level parallelism in C++ programs, which is not built in the default C++ compiler in recent versions of macOS. The simplest workaround is to install either LLVM or GCC as compilers.

Option 1. Install LLVM

LLVM is a collection of compiler and toolchain technologies. It contains Clang, a C++ compiler which delivers fast compiles, as well as other useful tools such as clang-format. It can be installed via Homebrew (be aware that the build might take a long time).

brew install --with-toolchain llvm

Option 2. Install gcc

An alternative to LLVM is GCC, GNU's Compiler Collection. Although slower than Clang, it can also be used to compile MXNet. It can easily be installed with Homebrew.

brew install gcc

3.3. Install ccache

Quoting the documentation, ccache is a compiler cache which speeds up recompilation by caching previous compilations and detecting when the same compilation is being done again.

brew install ccache

3.4. Install jemalloc

MXNet can use jemalloc for memory allocation, which is a general purpose malloc implementation that emphasizes fragmentation avoidance and scalable concurrency support.

```
brew install jemalloc
```

Step 4. CLion setup

Start by downloading CLion from JetBrains' website and installing it.

Once the installation process is finished, a welcome dialog will pop up. Choose **Open** > select the file **incubator-mxnet/CMakeLists.txt** > **Open as Project**.

Next, we will modify the preferences to use the C++ compiler we previously downloaded, as well as CMake and ccache. Open up the preferences window from CLion > Preferences (or +,) and proceed to the next step.

4.1. Select toolchain

- 1. In the preferences window (+,), search for toolchains.
- 2. Click on the + sign to add a toolchain, name it and set the paths of the C and C++ compilers. These paths will depend on the compiler you chose on step 3.2. If you followed the steps above, they should be:

	LLVM	GCC
C	/usr/local/Cellar/llvm/7.0.0/bin /clang	/usr/local/bin/gcc-8
C++	/usr/local/Cellar/llvm/7.0.0/bin /clang++	/usr/local/bin/g++-8

	DTD /2 edua ety /AnnaPL A	Preferences									
Q• toolchains 🛞	Build, Execution, Depl	oyment > Toolch	nains	Reset							
 Build, Execution, Deployment 	Default gcc	Name:	gcc								
									CMake:	Bundled	
		Make: Detected: /usr/bin/make	Detected: /usr/bin/make	•							
		C Compiler:	Detected: /Library/Developer/CommandLineTools/usr/bin/cc	-							
		C++ Compiler:	Detected: /Library/Developer/CommandLineTools/usr/bin/c++								
		Debugger:	Bundled LLDB								
	+- 6 • •		Version: 6.0								
			Cancel Apply	ОК							

() If you use Finder to browse for the compiler paths, use + + . to show hidden folders.

4.2. Build configuration

- In the preferences window, search for CMake, under the Build, Execution, Deployment section.
 Add a new profile using the + button on the bottom and give it a name of your choice.
 Set the toolchain to the one we defined in 4.1.

- 4. Define the CMake options (explained in the next step, 4.3).

	18 Imxnet option(US	E SSE "Build	with x86 SSE instr Preferen	uction support" UN IE NUI ARM) Ces			
Q		Build, Execution, Dep	Build, Execution, Deployment > CMake				
•	Appearance & Behavior Keymap	Automatically reloa Project is reloaded reg Profiles	Automatically reload CMake project on editing Project is reloaded regardless of this option on external changes, e.g. on VCS update offles				
	Plugins	Debug-gcc	Name:	Debug-gcc			
•	Version Control Build, Execution, Deployme	nt e	Build type:	Debug 👻 Toolchain: gcc	-		
	Toolchains		CMake options:	-DCMAKE_BUILD_TYPE=Debug -DCMAKE_C_COMPILER=/usr/loca	$\mathbb{1}_{k}^{\times}$		
	CMake			You can pass additional variables (-DVAR_NAME=value) and other options			
	Compilation Database		Environment:				
	Gradle						
	Debugger		Generation path:	CMAKE-DUIId-debug-gcc			
	Python Debugger						
			Build options:				
	 Console 						
	 Dynamic Analysis Tools 						
	Required Plugins						
►	Languages & Frameworks						
Þ	Tools	(+)- @ ▲ ▼					
2				Cancel Apply	ОК		

If changing the preferences does not have any effect, you may need to reset CMake's cache. To do so, go to Tools > CMake > Reset Cache and Reload Project.

4.3. Set CMake options

The following options are used in order to be able to compile in a Mac:

Option	Effect
-DUSE_CUDA=OFF	Disables CUDA. Unless your Mac has a GPU and CUDA installed, this option should be turned off.
-DBLAS=apple	Choose a BLAS (Basic Linear Algebra Subprograms) library. Setting it to 'apple' will select Apple's Accelerate.
-DUSE_OPENCV=OFF	Disable OpenCV, which is not installed on macOS by default.
-DCMAKE_CXX_COMPILER_LAUNCHER=/usr/local/opt /ccache/bin/ccache	Set the C, C++ and CUDA compilers to use ccache.
-DCMAKE_C_COMPILER_LAUNCHER=/usr/local/opt/ccache /bin/ccache	
-DCMAKE_CUDA_COMPILER_LAUNCHER=/usr/local/opt /ccache/bin/ccache	

Profiles							
Debug-llvm Debug-gcc	Name:	Debug-llvm					
	Build type:	Debug		Toolchain:	llvm		
	CMake options:	-DUSE_CUDA=OFF -DBLAS=apple -DUSE_OPENCV=OFF					
	Environment:	-DCMAKE_CXX_COMPI -DCMAKE_C_COMPILE	LER_L R_LAU	-AUNCHER=/u JNCHER=/usi	usr/local/opt/ccache/b r/local/opt/ccache/bin	in/ccac /ccache	he
	Generation path:						

For linux without CUDA you can use the following options:

-DUSE_CUDA=OFF

- -DUSE_OPENMP=ON
- -DUSE_OPENCV=ON -DUSE_MKL_IF_AVAILABLE=OFF
- -DCMAKE_VERBOSE_MAKEFILE=OFF
- -DCMAKE_CXX_COMPILER_LAUNCHER=ccache
- -DCMAKE_C_COMPILER_LAUNCHER=ccache
- -DCMAKE_CUDA_COMPILER_LAUNCHER=ccache

4.4. Run tests

To make sure everything is working properly, select mxnet_unit_tests as run configuration and run it.

To select specific unit tests, you can click Run "edit configurations" and add "-gtest_filter=" And a pattern like "SUITE.Test" such as --gtest_filter=" inv_khatri_rao.OneInputMatrixTransposed"

+ - @ / • • • • •	Name: mxnet_unit_tes				
► ■ Application					
Google Test					
In mxnet_unit_tests					
🕨 🏓 Python					
F Templates					
	Target:	mxnet_unit_tests			
	Program arguments:				
	Working directory:

	≪ Build				
	Prepare Test Run Show this page II A	activato to ol window			
	Show this page M A				
2			OK Cancel	Appl	У

Step 5. Select a style file (optional)

CLion provides code generation and formatting tools which can come in handy when developing. Coding style can be defined in the preferences dialogue to have CLion stick to certain coding guidelines. These can be loaded from an external style file, and they can be applied at project level or globally, at IDE level.

5.1. Loading a style file

As a reference, you can use the following style file: mxnet-style.xml.

To load the style file, go to **Preferences** > search for **code style** > change Scheme to **Project** (so the coding style will apply only to this project).

Next, click the settings icon () on the right > Import scheme > Intellij IDEA code style XML and browse for the style file.

			Prefer	ences			
ব্∙ code style	₿	Editor > Code	tor > Code Style				
Keymap		Scheme: Proje	ect Project	r ¢ .			
▼ Editor				Copy to IDE			
▼ General				Export			
Auto Import		Line separator:	System-Dependent	Import Scheme >	Intellij IDEA code style XML		
					JSCS config file		
Code Folding		Hard wrap at	120	columns 🗌 Wra	p on typing		
Code Folding							
Code Style		Visual guides:	Optional	columns			
C/C++							
CMake		Indents Detection					
OntforeContext		indents Detection					

You can use Google C++ coding style as the default since it's the one we use in MXNet:

Q . s tyle	Editor > Code Style > C/C++			
Editor	Scheme: Default IDE 👻 🌣		Sat From	
			Language	•
	Tabs and Indents Spaces Wrapping and Bra	aces Blank I	ines Code Generation New File Extens Predefined Style	e 🕨 Google
			#define OS NOT DEFINED	LLVM
			#endif	LLDB
			/**************************************	Qt
			*globalFunc	GNU
	Continuation indepts		void global Func():	Allman braces
				Whitesmiths brace
			namespace foo {	K&R braces
	Label indent:			
	Absolute label indent		*/	
	Indent in lambdas:		public:	
			Foo();	
	Indent members of classes:		~Foo();	
	Indent visibility keywords in class/structure:		<pre>virtual.Foo.*getSelT().{.returr</pre>	
			private:	
	Preprocessor directive indent:		<pre>void innerFunc();</pre>	
	Follow code indept		int.var;	
			}i	
			struct.FooPOD.{	
			#ifdef OS NOT_DEFINED	
			OK Cancel Apply	

B. Remote host development

Since version 2018.3 (it is an experimental version as of the writing of this page), CLion will support remote projects. Using this feature, it is possible to code locally in CLion and build, run and test on your remote machine. In order for this feature to work, you need:

- A local client machine, which can be either macOS, Windows or Linux, with CLion 2018.3 or newer.
- A Linux host, with rsync installed (unless your local machine is running Windows, in which case tar is needed)

To setup remote host development, simply:

- 1. Install the required tools (described in A.Step 3 of this guide specific installation commands will vary, as the remote has to run Linux) on your remote machine.
- 2. Follow this tutorial from Jetbrains' website to setup a remote toolchain and configure the SSH connection, as well as the mappings (where your project will be located on the remote host).
- 3. Set the appropriate CMake options. Section A.4.3 of this guide can be used s reference, although your options will depend on your remote host setup.

The first time you build remotely, CLion will sync your local files with the remote host. Depending on your connection, this process might take some time. If you have previously built your project locally, make sure to run make clean before the sync takes place, so there are less files to be copied.
